# Following the Human Thread in Social Navigation

Code available!

ICLR

**Objective:** Build a model allowing an agent to adapt to human movements in shared environments, approaching to assist when needed and stepping back to avoid collisions.

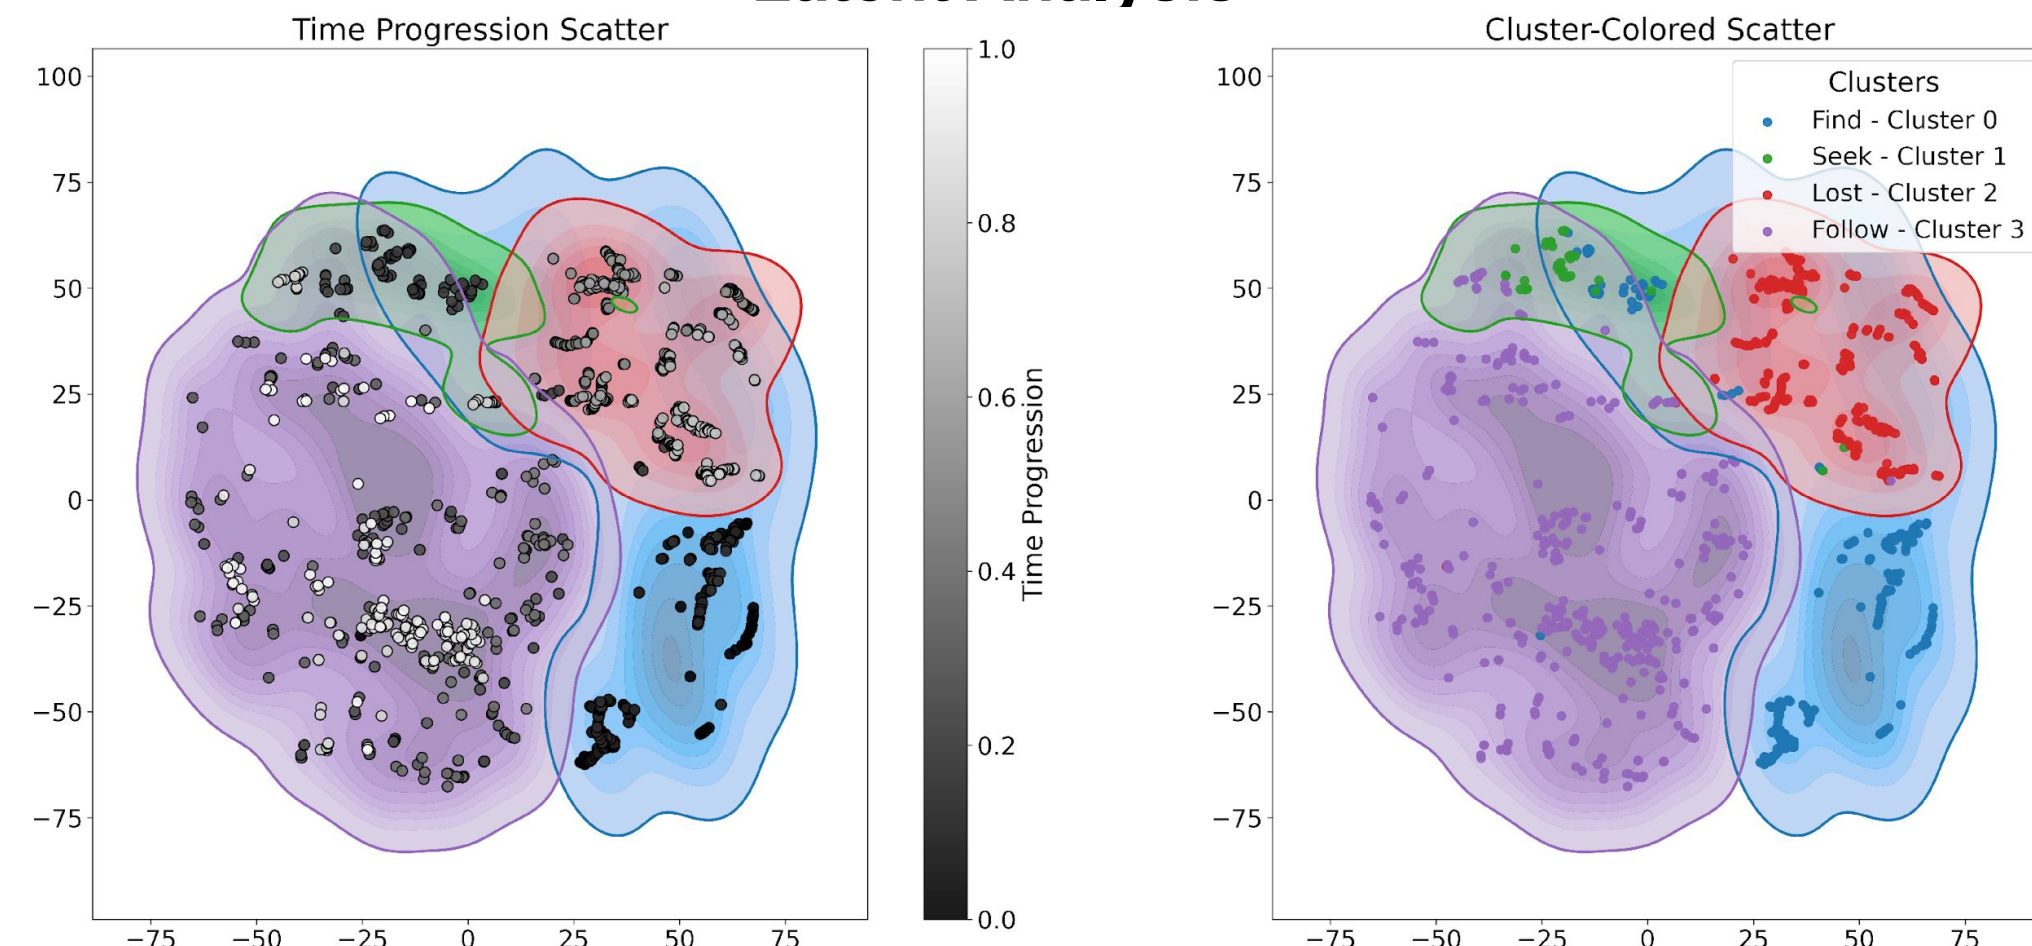

**Core Idea:** Infer social dynamics from the agent's past actions and states, without relying on hard-to-obtain privileged information.

## Social Dynamics Adaptation

We introduce Social Dynamics Adaptation (SDA): a two-stage reinforcement learning framework enabling robots to adapt to human movement.

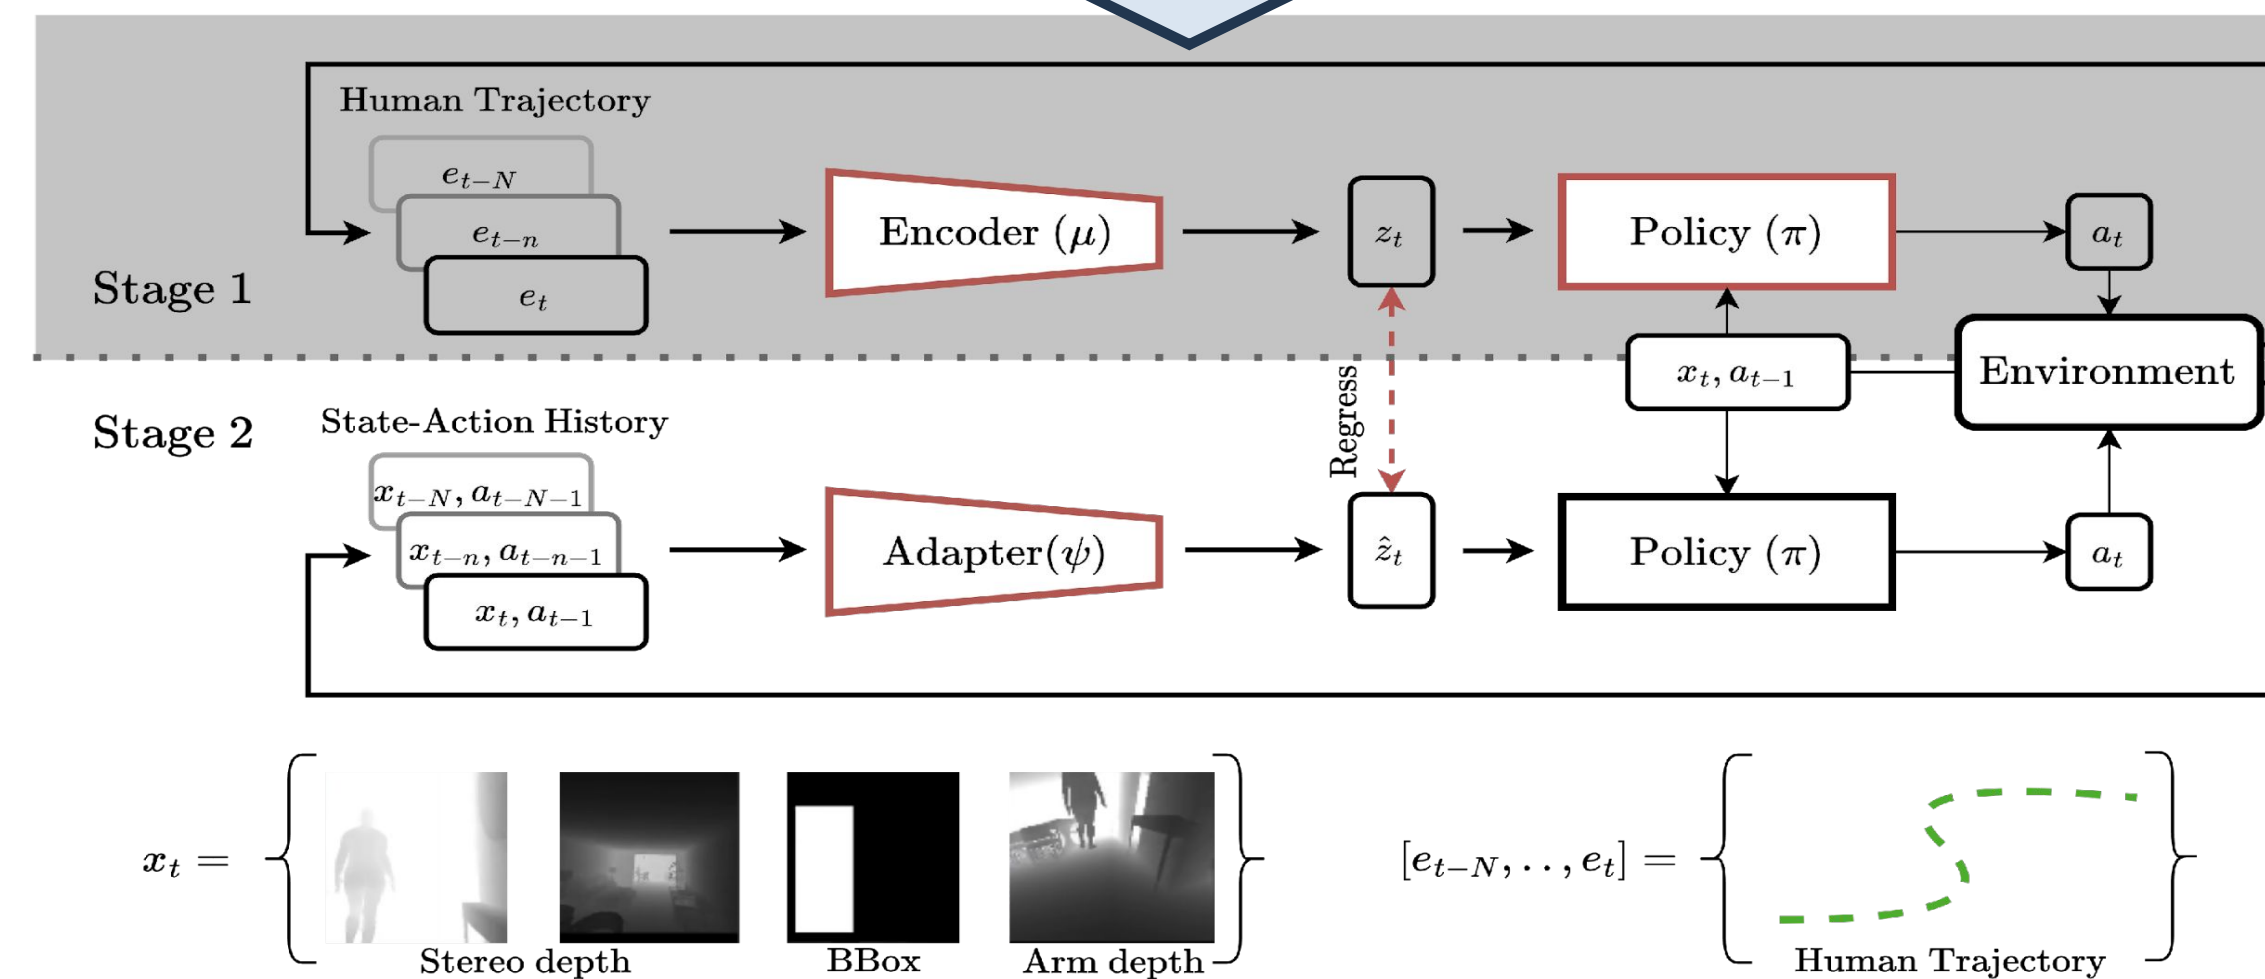

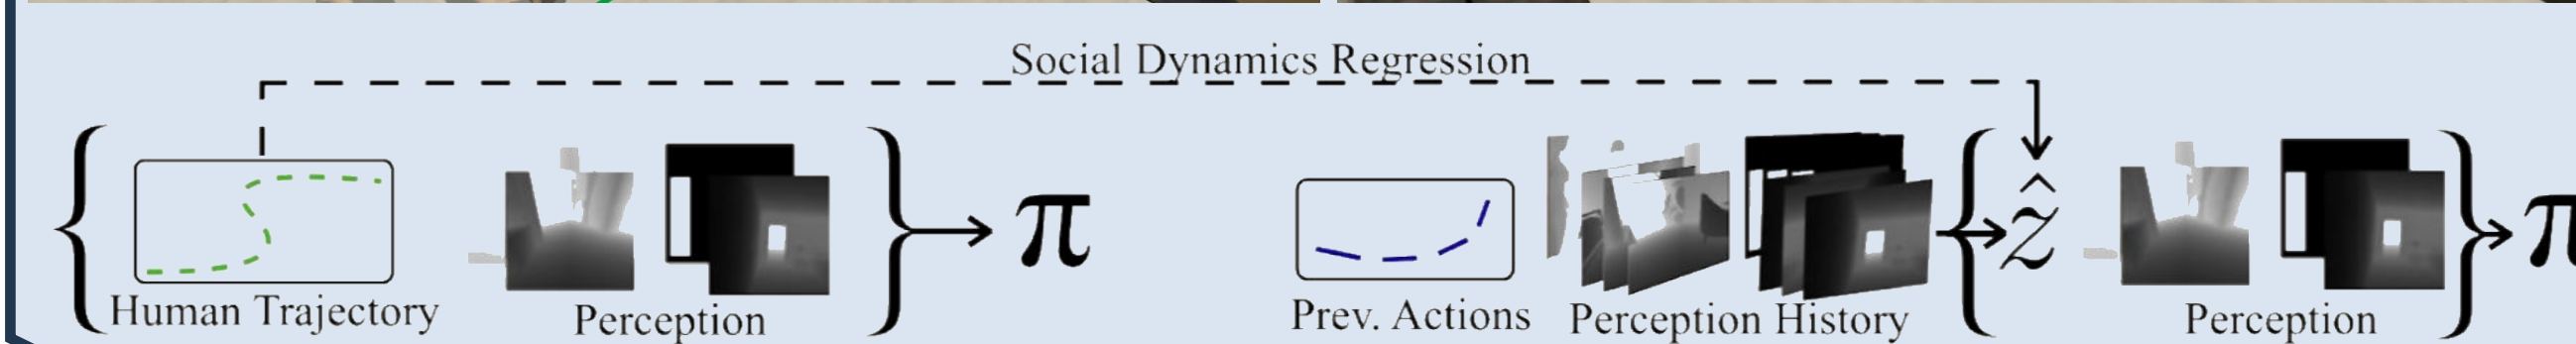

- Stage 1:** the model learns a latent representation of social dynamics from fully observable human trajectories (privileged information) to condition robot navigation.
- Stage 2:** SDA infers social dynamics solely from the robot's past actions and states, allowing real-time adaptation without external (privileged) trajectory data.

## Latent Analysis

**Acknowledgements.** We are grateful to Panasonic for partially supporting this work. We acknowledge the financial support from the PNRR MUR project PE0000013-FAIR and from the Sapienza grant RG123188B3EF6A80 (CENTS). Thanks CINECA and the ISCRA initiative for high-performance computing resources and support.

## Results

The SDA model was evaluated on the Habitat 3.0 simulator, showing state-of-the-art performance in finding and following humans:

- Success (S):** Increased from 76% to 91%. **(+15%)**
- Standardized Path Success (SPS):** Improved from 0.34 to 0.45. **(+11%)**
- Following Success (F):** Increased from 0.29 to 0.39. **(+10%)**

## Key Contributions

**Innovative Social Inference:** Introduces the novel SDA framework, enabling robots to infer social cues from their own past actions and states.

**Dual-Phase Learning:** Employs a two-stage RL approach: first building a latent representation of human movement, then adapting it in real time.

**Enhanced Navigation:** Evaluated on Habitat 3.0, SDA significantly improves the robot's ability to detect and follow humans.
